

SP3238

Intelligent +3.0V to +5.5V RS-232 Transceiver

FEATURES

- Meets true EIA/TIA-232-F Standards from a +3.0V to +5.5V power supply
- Interoperable with EIA/TIA-232 and adheres to EIA/TIA-562 down to a +2.7V power source
- **AUTO ON-LINE**[®] circuitry automatically wakes up from a 1μA shutdown
- Minimum 250Kbps data rate under load
- Regulated Charge Pump Yields Stable RS-232 Outputs Regardless of V_{cc} Variations
- ESD Specifications: ±2kV Human Body Model

Now Available in Lead Free Packaging

DESCRIPTION

The SP3238 device is an RS-232 transceiver solution intended for portable or hand-held applications such as notebook and palmtop computers. The SP3238 uses an internal high-efficiency, charge-pump power supply that requires only $0.1\mu F$ capacitors in 3.3V operation. This charge pump and Sipex's driver architecture allow the SP3238 device to deliver compliant RS-232 performance from a single power supply ranging from +3.0V to +5.0V. The SP3238 is a 5-driver/3-receiver device, ideal for laptop/notebook computer and PDA applications. The SP3238 includes one complementary receiver that remains alert to monitor an external device's Ring Indicate signal while the device is shutdown.

The **AUTO ON-LINE**® feature allows the device to automatically "wake-up" during a shutdown state when an RS-232 cable is connected and a connected peripheral is turned on. Otherwise, the device automatically shuts itself down drawing less than $1\mu A$.

SELECTION TABLE

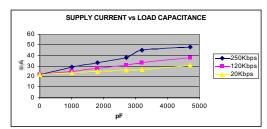

Figure 3. Supply Current VS. Load Capacitance when Transmitting Data

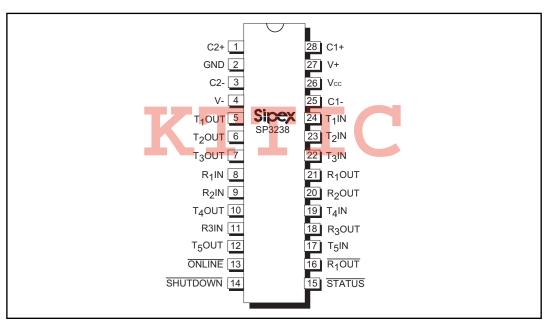

Figure 4. SP3238 Pinout Configuration

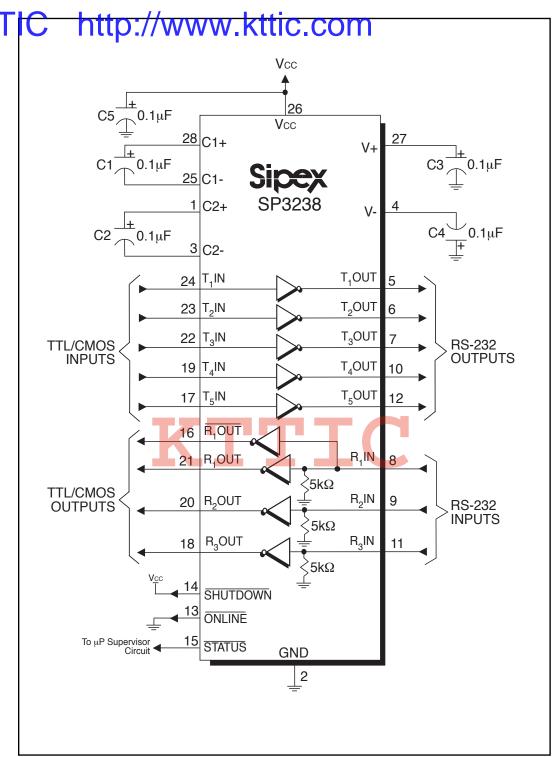

Figure 5. SP3238 Typical Operating Circuit

KTT468 RIPTIPALTD://www.kttic.com

The SP3238 device meets the EIA/TIA-232 and ITU-T V.28/V.24 communication protocols and can be implemented in battery-powered, portable, or hand-held applications such as notebook or palmtop computers. The SP3238 device features Sipex's proprietary and patented (U.S. #5,306,954) on-board charge pump circuitry that generates ±5.5V RS-232 voltage levels from a single +3.0V to +5.5V power supply. The SP3238 device can guarantee a data rate of 250kbps fully loaded.

The SP3238 is a 5-driver/3-receiver device, ideal for portable or hand-held applications. The SP3238 includes one complementary always-active receiver that can monitor an external device (such as a modem) in shutdown. This aids in protecting the UART or serial controller IC by preventing forward biasing of the protection diodes where V_{CC} may be disconnected.

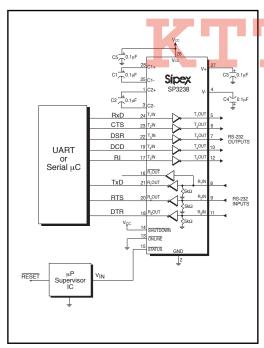

Figure 6. Interface Circuitry Controlled by Microprocessor Supervisory Circuit

The SP3238 device is an ideal choice for power sensitive designs. The SP3238 device features **AUTO ON-LINE®** circuitry which reduces the power supply drain to a 1μA supply current. In many portable or hand-held applications, an RS-232 cable can be disconnected or a connected peripheral can be turned off. Under these conditions, the internal charge pump and the drivers will be shut down. Otherwise, the system automatically comes online. This feature allows design engineers to address power saving concerns without major design changes.

THEORY OF OPERATION

The SP3238 device is made up of four basic circuit blocks: 1. Drivers, 2. Receivers, 3. the Sipex proprietary charge pump, and 4. **AUTO ON-LINE**® circuitry.

Drivers

The drivers are inverting level transmitters that convert TTL or CMOS logic levels to 5.0V EIA/TIA-232 levels with an inverted sense relative to the input logic levels. Typically, the RS-232 output voltage swing is ±5.4V with no load and ±5V minimum fully loaded. The driver outputs are protected against infinite short-circuits to ground without degradation in reliability. These drivers comply with the EIA-TIA-232F and all previous RS-232 versions.

The drivers can guarantee a data rate of 250kbps fully loaded with $3k\Omega$ in parallel with 1000pF, ensuring compatibility with PC-to-PC communication software. All unused driver inputs must be connected to V_{CC} or GND.

The slew rate of the driver output is internally limited to a maximum of 30V/µs in order to meet the EIA standards (EIA RS-232D 2.1.7, Paragraph 5). The transition of the loaded output from HIGH to LOW also meets the monotonicity requirements of the standard.

figure 7 shows it oppose khast dividual to lest the RS-232 Drivers. Figure 8 shows the test results of the loopback circuit with all five drivers active at 120kbps with typical RS-232 loads in parallel with 1000pF capacitors. Figure 6 shows the test results where one driver was active at 250kbps and all five drivers loaded with an RS-232 receiver in parallel with a 1000pF capacitor. A solid RS-232 data transmission rate of 120kbps provides compatibility with many designs in personal computer peripherals and LAN applications.

Receivers

The receivers convert ±5.0V EIA/TIA-232 levels to TTL or CMOS logic output levels.

Receivers are not active when in shutdown. If there is no activity present at the receivers for a period longer than $100\mu s$ during AUTO ON-LINE® mode or when $\overline{SHUTDOWN}$ is enabled, the device goes into a standby mode where the circuit draws $1\mu A$.

The truth table logic of the driver and receiver outputs can be found in Table 2.

The SP3238 includes an additional non-inverting receiver with an output R₁OUT. R₁OUT is an extra output that remains active and monitors activity while the other receiver outputs are forced into high impedance. This allows Ring

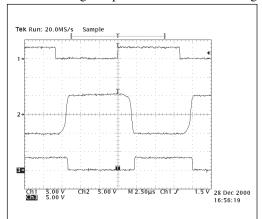

Figure 8. Loopback Test Circuit Result at 120kbps (All Drivers Fully Loaded)

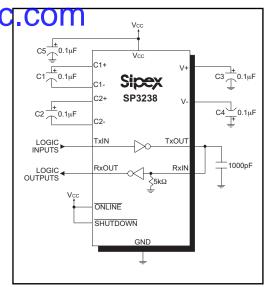

Figure 7. Loopback Test Circuit for RS-232 Driver Data Transmission Rates

Indicator (RI) from a peripheral to be monitored without forward biasing the TTL/CMOS inputs of the other devices connected to the receiver outputs.

Since receiver input is usually from a transmission line where long cable lengths and system interference can degrade the signal, the inputs have a typical hysteresis margin of 300mV. This ensures that the receiver is virtually immune to

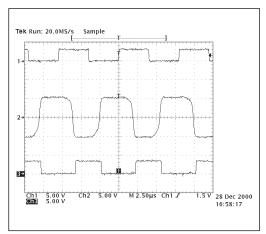

Figure 9. Loopback Test Circuit result at 250kbps (All Drivers Fully Loaded)

notsy transmissiph lines. Should an input be left unconnected, an internal 5kΩ pulldown resistor to ground will commit the output of the receiver to a HIGH state.

Charge Pump

The charge pump is a Sipex-patented design (U.S. #5,306,954) and uses a unique approach compared to older less-efficient designs. The charge pump still requires four external capacitors, but uses a four-phase voltage shifting technique to attain symmetrical 5.5V power supplies. The internal power supply consists of a regulated dual charge pump that provides output voltages 5.5V regardless of the input voltage (V_{CC}) over the +3.0V to +5.5V range. This is important to maintain compliant RS-232 levels regardless of power supply fluctuations.

The charge pump operates in a discontinuous mode using an internal oscillator. If the output voltages are less than a magnitude of 5.5V, the charge pump is enabled. If the output voltages exceed a magnitude of 5.5V, the charge pump is disabled. This oscillator controls the four phases of the voltage shifting (Figure 13). A description of each phase follows.

Phase 1 (Figure 11)

— V_{SS} charge storage — During this phase of the clock cycle, the positive side of capacitors C_1 and C_2 are initially charged to V_{CC} . C_1 + is then switched to GND and the charge in C_1 - is transferred to C_2 -. Since C_2 + is connected to V_{CC} , the voltage potential across capacitor C_2 is now 2 times V_{CC} .

Phase 2 (Figure 12)

— V_{SS} transfer — Phase two of the clock connects the negative terminal of C_2 to the V_{SS} storage capacitor and the positive terminal of C_2 to GND. This transfers a negative generated voltage to C_3 . This generated voltage is regulated to a minimum voltage of -5.5V. Simultaneous with the transfer of the voltage to C_3 , the positive side of capacitor C_1 is switched to V_{CC} and the negative side is connected to GND.

— V_{DD} charge storage — The third phase of the clock is identical to the first phase — the charge transferred in C_1 produces – V_{CC} in the negative terminal of C_1 , which is applied to the negative side of capacitor C_2 . Since C_2 + is at V_{CC} , the voltage potential across C_2 is 2 times V_{CC} .

Phase 4 (Figure 15)

— V_{DD} transfer — The fourth phase of the clock connects the negative terminal of C_2 to GND, and transfers this positive generated voltage across C_2 to C_4 , the V_{DD} storage capacitor. This voltage is regulated to +5.5V. At this voltage, the internal oscillator is disabled. Simultaneous with the transfer of the voltage to C_4 , the positive side of capacitor C_1 is switched to V_{CC} and the negative side is connected to GND, allowing the charge pump cycle to begin again. The charge pump cycle will continue as long as the operational conditions for the internal oscillator are present.

Since both V+ and V- are separately generated from V_{CC} , in a no-load condition V+ and V- will be symmetrical. Older charge pump approaches that generate V- from V+ will show a decrease in the magnitude of V- compared to V+ due to the inherent inefficiencies in the design.

The clock rate for the charge pump typically operates at 500kHz. The external capacitors can be as low as $0.1\mu F$ with a 16V breakdown voltage rating.

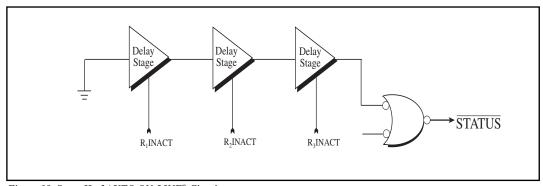

Figure 18. Stage II of AUTO ON-LINE® Circuitry

KTT W ON PHILE PIPE WWW. Kttic.com

The SP3238 device has a patent pending **AUTO ON-LINE**® circuitry on board that saves power in applications such as laptop computers, palmtop (PDA) computers, and other portable systems.

The SP3238 device incorporates an AUTO ON-LINE® circuit that automatically enables itself when the external transmitters are enabled and the cable is connected. Conversely, the AUTO ON-LINE® circuit also disables most of the internal circuitry when the device is not being used and goes into a standby mode where the device typically draws 1µA. This function is externally controlled by the ONLINE pin. When this pin is tied to a logic LOW, the AUTO ON-LINE® function is active. Once active, the device is enabled until there is no activity on the receiver inputs. The receiver input typically sees at least $\pm 3V$, which are generated from the transmitters at the other end of the cable with a $\pm 5V$ minimum. When the external transmitters are disabled or the cable is disconnected, the receiver inputs will be pulled down by their internal $5k\Omega$ resistors to ground. When this occurs over a period of time, the internal transmitters will be disabled and the device goes into a shutdown or standby mode. When ONLINE is HIGH, the AUTO ON-LINE® mode is disabled.

The **AUTO ON-LINE**® circuit has two stages:

- 1) Inactive Detection
- 2) Accumulated Delay

The first stage, shown in Figure 17, detects an inactive input. A logic HIGH is asserted on R_XINACT if the cable is disconnected or the external transmitters are disabled. Otherwise, R_XINACT will be at a logic LOW. This circuit is duplicated for each of the other receivers.

The second stage of the AUTO ON-LINE® circuitry, shown in Figure 18, processes all the receiver's R_X INACT signals with an accumulated delay that disables the device to a 1μ A supply current.

The STATUS pin goes to a logic LOW when the cable is disconnected or when the external transmitters are disabled.

When the drivers or internal charge pump are disabled, the supply current is reduced to $1\mu A$. This can commonly occur in hand-held or portable applications where the RS-232 cable is disconnected or the RS-232 drivers of the connected peripheral are turned off.

The AUTO ON-LINE® mode can be disabled by the SHUTDOWN pin. If this pin is a logic LOW, the AUTO ON-LINE® function will not operate regardless of the logic state of the ONLINE pin. Table 2 summarizes the logic of the AUTO ON-LINE® operating modes and the truth table logic of the driver and receiver outputs.

The STATUS pin outputs a logic LOW signal when there is no valid RS-232 signal present on any receiver input. This pin goes to a logic HIGH when the external transmitters are enabled and the cable is connected.

When the SP3238 device is shut down, the charge pump is turned off. V+ charge pump output decays to V_{CC} , the V- output decays to GND. The decay time will depend on the size of capacitors used for the charge pump. Once in shutdown, the time required to exit the shut down state and have valid V+ and V- levels is typically 200ms.

For easy programming, the STATUS pin can be used to indicate DTR or a Ring Indicator signal. Tying ONLINE and SHUTDOWN together will bypass the AUTO ON-LINE® circuitry so this connection acts like a shutdown input pin.

KTT#©ਾ०=##Nqp://www.kttic.com

The SP3238 device incorporates ruggedized ESD cells on all driver output and receiver input pins. The ESD structure is improved over our previous family for more rugged applications and environments sensitive to electro-static discharges and associated transients.

The Human Body Model has been the generally accepted ESD testing method for semiconductors. This method is also specified in MIL-STD-883, Method 3015.7 for ESD testing. The premise of this ESD test is to simulate the human body's potential to store electro-static energy and discharge it to an integrated circuit. The simulation is performed by using a test model as shown in Figure 19. This method will test the IC's capability to withstand an ESD transient during normal handling such as in manufacturing areas where the ICs tend to be handled frequently.

For the Human Body Model, the current limiting resistor (R_s) and the source capacitor (C_s) are 1.5k Ω and 100pF, respectively.
